I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1985 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

NETWORK ARRANGEMENT FOR COMMUNICATION

Field of the Invention

5 This invention relates to a secure method and network arrangement for communication.

Background to the Invention

10 Subscribers of communication services on fixed or mobile networks register terminals for use within a given network with the operator of that network. The network operator can thus deliver relevant subscriber services and support call origination and delivery for that registered terminal. For
15 example, following user registration, the network can perform call set up, call routing and billing functions. Where a subscriber is mobile and visits another network, communication services may still be available by means of roaming agreements between the network operators.

20

Internet applications and particularly wireless Internet applications have been proposed which allow subscribers of secure local networks to choose between communication routes which are deemed relatively secure and alternative
25 communication routes which are inherently less secure. The Internet is regarded as providing insecure communication routes, particularly when compared with traditional communication networks such as a fixed-cable telecommunication network or a mobile telecommunication network. Accordingly,
30 if a terminal located in a first secure network wishes to communicate with a terminal located in a second secure network, the intermediate communication route can either be secure or insecure. For example an intermediate network such as the PSTN or ISDN networks would be deemed relatively
35 secure. However, an intermediate network incorporating the Internet would render the communication route insecure.

Where an insecure network is used the originating and destination end terminals may use an encryption technique.

5 Applications for implementing the chosen encryption technique
need to be provided at both the originating and destination
end terminals. In practice, situations arise where a plurality
of end terminals in one network wish to communicate with a
plurality of end terminals in another network and mutually
10 compatible encryption applications must be provided to each of
the plurality of end terminals.

Security services employed on fixed and mobile networks
include encryption, certification and authentication.
15 Encryption, for example, typically employs systems based on
key pairs. That is, before transmission a subscriber protects
the transmission by running an encryption application on the
originating end terminal using a key. The transfer is made
with the content of the message in an encrypted (protected)
20 format. At the destination end terminal, the message is
decrypted by running a mutually compatible decryption
application also with a key.

One well known type of encryption application employs a
25 "private/public key pair system", where the originating
subscriber protects his transmission using a private key and
the message is then transferred via an intermediate network to
an end terminal where it can be decrypted by the destination
subscriber by means of a public key. This system requires that
30 the originating subscriber makes the relevant public key
available to the or each destination subscriber. Subscribers
do not usually make private keys available. Options for making
public keys available to destination subscribers include, for
example, email or posting the key on web sites which are
35 accessible to destination subscribers. Although the keys are
available to the intended recipients, this system is
inconvenient and vulnerable to those who are intent on
obtaining public keys for deciphering messages not intended
for them. Imitation (hoax) web sites have been used to
40 manipulate such arrangements.

5 Another type of key system employed in encryption applications
is the "shared secret key pair system". This system requires
that the originating subscriber protects his transmission
using a secret key and the terminating subscriber uses the
same key (shared secret key) to extract the message
10 information. This system differs from the private/public key
pair system in that it requires that each receiving subscriber
has access to the senders secret key. This arrangement is only
acceptable where there is a high degree of trust between
originating and receiving subscribers and secure networks
15 therebetween.

In general, encryption techniques require that both the
communicating end terminals of the subscribers have access to
the relevant encryption/decryption algorithms/keys etc. The
20 communicating end terminals must also be provided with and be
able to run a suitable application. Any changes or
modifications to the encryption technique at the originating
end must be provided to the relevant terminal at the receiving
end.

25

Summary of the Invention

Embodiments of the present invention seek to address the
problems outlined hereinbefore.

30

According to an aspect of the present invention there is
provided a network arrangement for the distribution of
security information between a first node in a first secure
network and one or more nodes in a second secure network, said
35 first and second networks being separated by a relatively
insecure network, wherein communications from said first node
to one or more of said second nodes via said relatively
insecure network are encrypted, the network arrangement
comprising one or more network elements operable to store
40 security information and triggerable to distribute said
security information in a secure manner from said first node

5 to one or more target nodes in said second secure network.

According to a second aspect of the present invention there is provided a network arrangement for the distribution of encryption/decryption information between a first node in a
10 first secure network and one or more nodes in a second secure network, said first and second networks being separated by a relatively insecure network, wherein communications from said first node to one or more of said second nodes via said relatively insecure network are encrypted, the network
15 arrangement comprising one or more network elements operable to store encryption/decryption information and triggerable to distribute decryption information in a secure manner from said first node to one or more target nodes in said second secure network.

20

Typically, the decryption information includes algorithms and/or keys. Preferably, the one or more network elements comprise switch means provided with control means, and storage means for storing said encryption/decryption information and
25 the switch means is operable to selectively distribute an algorithm and/or key in response to a predetermined type of communication. In preferred embodiments, said predetermined type of communication is identified by means of one or more of the following: recognition of originating subscriber
30 characteristics, recognition of destination subscriber characteristics; recognition of payload characteristics or recognition of network service characteristics.

In other embodiments, distribution of the decryption
35 information is triggered according to predetermined time schedules by an intelligent peripheral communicating with said network element.

Network arrangements according to the invention allow the
40 distribution of decryption information to end terminals in the second network and/or to a node within the second network

5 other than the destination end terminal for the communication in question. Preferred network elements may be located, for example, substantially within said first network or substantially within said second network, possibly at different levels of hierarchy.

10

According to a third aspect of the present invention there is provided a method for the distribution of security information between a first node in a first secure network and one or more nodes in a second secure network, said first and second
15 networks being separated by a relatively insecure network, wherein communications from said first node to one or more of said second nodes via said relatively insecure network are encrypted, the method including the step of providing one or more network elements operable to store security information
20 and triggerable to distribute said security information in a secure manner from said first node to one or more target nodes in said second secure network.

According to a fourth aspect of the present invention there is
25 provided a method for the distribution of encryption/decryption information between a node in a first secure network and one or more nodes in a second secure network, said first and second networks being separated by a relatively insecure network, wherein communications from said
30 first node to one or more of said second nodes via said relatively insecure network are encrypted, the method including the step of providing one or more network elements operable to store encryption/decryption information and triggerable to distribute decryption information in a secure
35 manner from said first node to one or more target nodes in said second secure network.

According to a fifth aspect of the present invention there is provided a network arrangement for the distribution of
40 security information between a first node and one or more second nodes including one or more network elements operable

- 5 to store security information and triggerable to distribute the security information from said first node to one or more of said second nodes.

According to a sixth aspect of the present invention there is
10 provided a method for the distribution of security information between a first node and one or more second nodes, including the step of providing one or more network elements operable to store security information and triggerable to distribute the security information from said first node to one or more of
15 said second nodes.

Preferred embodiments have applications, for example, in distributing algorithms and/or keys between nodes in secure networks over a relatively insecure intermediate network but
20 also in distributing algorithms and/or keys and/or secure numbers or bitstrings etc. over different network arrangements. Examples of uses include in ECASH (electronic cash) applications.

25 Brief Description of Drawings

For a better understanding of the present invention and to understand how the same may be brought into effect, reference will now be made by way of example only to the following
30 Figures in which:

Figure 1 schematically illustrates examples of alternative communication routes between a first end terminal in a first network and a second end terminal in a second network;

35

Figure 2 schematically illustrates a preferred method for communication between first and second end terminals located in secure networks and separated by an insecure network;

40 Figure 3 schematically illustrates the method of Figure 2 applied to communication to and from a roaming mobile

5 terminal;

Figure 4 schematically illustrates a preferred method for the distribution of encryption information or other security information; and

10

Figure 5 schematically illustrates a second method for the distribution of encryption information or other security information;

15. Figure 6 schematically illustrates another method for the distribution of security information.

Figure 7 schematically illustrates another method for the distribution of security information.

20

Description of Preferred Embodiments of the Invention

The term "encryption" used herein can refer either to direct encryption of the IP payload, possibly with addition of an encryption header, or tunnelled payloads (i.e. not only
25 encrypting but adding a further network header to address the encrypted packets to a known tunnel end point). The term is also used in a broader sense to refer to general compression techniques. The term "key" can refer to encryption/decryption
30 keys and secure codes/numbers used, for example, in electronic cash applications.

Figure 1 shows a first end terminal 10 wishing to communicate with a second end terminal 12. The originating end terminal
35 10 is in a first network (A) controlled by a first network operator and the second end terminal 12 is located in a second network (B) controlled by a second network operator. The networks (A) and (B) may be fixed or mobile networks operated by trusted network operators and are thus deemed relatively
40 secure. The networks (A) and (B) are separated by intermediate networks which, in this example, include a public

5 switched telephone network PSTN 16 and the Internet 22. Whereas the PSTN 16 could be regarded as a relatively secure intermediate network for transfer between the end terminals 10 and 12, the Internet 22 would be regarded as an insecure network.

10

Switch 14 represents a general service switching point, for example a mobile switching centre (MSC) or any suitable telecommunications switch or routing element. Communications can occur between the first end terminal 10 and the second end terminal 12 via a secure intermediate route indicated by arrows 19, shown here as via the PSTN 16. Alternatively, communication between the first and second end terminals 10 and 12 can occur via an insecure intermediate route indicated by arrows 20, shown here as including the Internet 22.

20

Referring now to Figure 2, a first preferred method for communication provides a secure network arrangement including a network element which permits the construction of a tunnel through the insecure network between first and second end points within the secure networks of the originating and terminating end terminals, respectively. The effect is to create a virtual private network (VPN) for secure communication between the two terminals 10 and 12. A group of logically associated intelligent network elements 30 are provided in a secure network between the first end terminal 10 and the terminating end terminal 12. In this example, the intelligent network elements 30 are provided in the network (A) of the originating end terminal 10. The intelligent network elements 30 can communicate with end terminal 10 and also communicate with an encryption engine 40 in the first network (A).

The intelligent network elements 30 include a service switching point (SSP) 32, a service control point (SCP) 34 for providing an intelligent function, a service data base (SDB) 36 for storing subscriber profiles and an intelligent

40

5 peripheral (IP) 38. The service switching point 32 can transfer messages from and/or to the first end terminal 10 and one or more of the intermediate networks 16,22. The service switching point 32 is connected to the service control point 34 which has processor functionality and access to the service
10 database 36. The intelligent peripheral 38 is also connected to the service control point 34.

To communicate with either of the intermediate networks, the service switching point 32 can transfer messages to and/or
15 from either the PSTN 16 or the encryption engine 40 which defines a first end point of a tunnel 41 through the Internet 22. A further switch 18 is provided in the second network (B). The switch 18 is connected to each of the intermediate networks, namely the PSTN 16 and a second end point 42 of the
20 Internet tunnel 41, and with the second end terminal 12. Note that the encryption engine 40 defining one end point of the tunnel 41 and the other end point 42 of the tunnel 41 are located in the first and second secure networks (A) and (B), respectively. The tunnel 41 is thus constructed as a secure
25 passageway for transfer through the Internet 22.

The intelligent network elements 30 enable the operator of the first network (A) to offer subscribers a secure communication route over a usually insecure network. This is achieved by
30 intelligent management of route and encryption techniques in respect of specific subscribers or groups of subscribers. In a situation where the first end terminal 10 wishes to communicate with the second end terminal 12 via the Internet 22, the first terminal 10 originates the communication and
35 follows access 50 and connection set-up 52 procedures. Typically the end terminal 10 transmits both an identification number and a destination number on a control channel. The service switching point 32 receives the information from terminal 10 and can refer to the service control point 34 in
40 response to a predetermined trigger. The type of trigger employed can vary but will generally be set-up such that the

5 intelligent network elements 30 provide the subscriber of the
end terminal 10 with his preferred network service. For
example, the service switching point 32 can be set up to refer
to the service control point 34 in response to a trigger being
set, for example, on the network address of the originating 10
10 or terminating 12 end terminals, on flow ID which is an
identity associated with a succession of packets and/or or on
payload information. In this example, the trigger is set to
respond to a characteristic of the destination number. In
other embodiments, the service switching point 32 may
15 recognise a range of numbers in the originating ID number,
and/or destination number or may respond to prepaid only,
voice only, data only messages, and be dependent on time-of-
day etc. This list of possible triggers is obviously not
exhaustive.

20

When a referral by the service switching point 32 to the
service control point 34 has been triggered as described
above, the service control point 34 accesses the relevant
subscriber profile stored in the service database 36. The
25 subscriber profile contains subscriber specific information
including information regarding the network services paid for
by each subscriber or group of subscribers. In this example,
the subscriber profile contains subscriber specific routing
and encryption information which is taken into account
30 whenever a trigger is determined. The information stored in
the service database 36 may include one or more preferred
encryption algorithms (or compression algorithms etc.) and/or
keys. Subscriber specific profile information is then
returned to service switching point 32 via service control
35 point 34 and the transfer is routed as appropriate. If the
subscriber in question prefers communication between the first
network (A) and the second network (B) to go via the PSTN 16,
the profile information will indicate this and the service
switching point 32 will direct the transfer accordingly.
40 However, if the subscriber in question prefers communication
between the first network (A) and the second network (B) to go

5 via the Internet 22, then the service switching point 32 will
redirect the communication to the encryption engine 40 where
the message content is automatically encrypted using an
algorithm. In this example, the preferred algorithm is part
of the subscriber specific information specified in the
10 service database 36. Once encrypted, the message content
enters the Internet tunnel 41 where it remains in an encrypted
format while it traverses the Internet, i.e. until it reaches
the end point 42 located within the secure network (B).

15 . The provision of triggered redirection and, where appropriate,
automatic encryption permits a secure tunnel 41 to be
constructed through the usually insecure Internet. From the
end point 42 the message is routed on to switch 18 and
thereafter to the destination end terminal 12. Between the
20 end terminals 10,12 and their respective access switches (i.e.
the service switching point 32 and the switch 18) in the
access networks (e.g. GSM or GPRS) specific encryption or
physical security is used and thereby provides inherent
security within the first and second networks (A) and (B).

25

Any information held in the service database 36 can be easily
modified or changed without down-loading or up-loading to and
from end terminals 10,12. For example modifications can effect
updates of stored algorithms/keys or alter group lists to
30 permit guest users of a subscriber to benefit from the
service. The modifications may be made, for example, via an
intelligent network service management access point (SMAP)
which allows the operator or even the subscriber himself to
change the database 36 records constituting the subscriber
35 profile information as appropriate.

Preferred methods therefore provide a secure method of
communication, wherein triggers set on say originating
subscriber identity, destination subscriber number, IP
40 address, flow ID or payload information can be mapped to
intelligent network service logic available to the subscriber.

5 Preferred arrangements in effect permit the creation of a
virtual private network (VPN) for communication between the
end terminals 10 and 12. Preferred arrangements represent a
triggered intelligent network service on an intermediate-
10 system (i.e. on a switch/router within a network), rather than
an application based system operating on end terminals. An
advantage is that the same service can be triggered for any
subscriber and, if desired, the algorithms or keys used in
encryption can be proprietary to a subscriber. Paying
15 subscribers can benefit from the advantages, whether they are
in home or visitor networks provided the network operators of
the relevant home and visited networks are party to a roaming
agreement.

Individuals or commercial entities who are subscribers and
20 have paid for specific services will be identified in the
group lists held within the service data base and can benefit
from a secure network service customised according to their
own preferences.

25 Another advantage is that commercial entities or other group
subscribers can define an algorithm to be used exclusively in
connections between members of a specific group. That is,
company A could define an algorithm to be used in transfers
between employees of company A only; in which case when
30 establishing a connection between company A employees, the
service control point 34 would inform the service switching
point 32 to forward an encryption algorithm specific to
company A to the encryption engine 40.

35 Another advantage is that because handling of encryption is in
fact network based there is no need to store encryption or
compression algorithms or the like at either of the respective
end terminals 10,12.

40 Intelligent network elements 30 can cause encryption keys or
even encryption algorithms themselves to be loaded and used at

5 encryption end points associated with the service switching
point 32. The encryption engine 40 may, but does not need to
be, part of the intelligent network elements 30 served
directly by the service switching point 32 which triggers the
service. For example, the triggering service switching point
10 32 may simply redirect packets or flows of a specific
subscriber to an encryption engine 40 on a separate
network/sub-network, by re-routing to the relevant host in
order to enter the encryption engine 40. Of course, a
decryption point would still need to be located before or at
15 the end point 42 or at least within the secure network (B).

In one modified version the algorithm is run in a centralised
encryption (or compression etc) network element (NE) separate
from the service switching point 32 but still within the first
20 network (A). In this case, the service control point 34
returns routing instructions (e.g. a tunnel to the NE) and any
encryption parameters to be used in the encryption NE.
Corresponding means may be provided within the second network
(B) to effect decryption/de-compression of the message.

25

In another modified version, the service is triggered in
response to a specific message sent by the source terminal.
That is, the service is specifically commanded by the end
terminal in communication.

30

In another modified version, the intelligent peripheral 38 is
connected directly to the SSP 32.

In another modified version, the service switching point 32
35 may refer to the service control point 34 as a matter of
course. (i.e. without a trigger being recognised). The
records in the service data base then being accessed by the
service control point 34 to determine specific routing
instructions and encryption/decryption information.

40

Where roaming agreements are in place between the operators of

5 networks (A) and (B), corresponding secure network services
can be provided on service switching points in the visited
network. These service switching points may run algorithms set
up in advance through agreement between the network operators
or transferred dynamically, for example upon an end terminal
10 attaching to a visited network. Alternatively, distribution
of the necessary encryption/decryption information may be
achieved via a secure virtual home environment (VHE) mechanism
or by a distribution method/arrangement described hereinafter.

15 . Figure 3 shows how a roaming agreement set up between the
operators of networks (A) and (B) may allow originating end
terminal 10 to benefit from the advantages of the preferred
method while visiting network (B). End terminal 10 in effect
experiences a virtual home environment (VHE) facilitated by
20 secure communications between the network operators party to
the agreement. The virtual home environment enables terminal
10 to initiate the normal access 50 and connection set up 52
operations as if it was located in its home network. If the
subscriber of end terminal 10 normally benefits from secure
25 network communications provided by his home network operator,
a trigger set up using intelligent network elements 60, as
mentioned above will be identified in the service switching
point 62. If no such trigger is identified the service
switching point will route the call via the PSTN 16 or via the
30 Internet 22 non securely. Where a trigger is identified by the
service switching point 62, the service control point 64
accesses the service database 66 in which the subscriber
profile contains encryption information. According to the
profile information contained in service database 36, in this
35 example routing information, encryption information and group
subscriber lists, etc., the service control point 64 controls
the service switching point 62 to redirect the call in a
secure manner via the Internet 22. As before, the message
would then be redirected to an encryption engine 80 where the
40 message is encrypted before it enters a tunnel 41 for secure
transfer through the Internet 22 to a secure end point 82

5 within the destination network (A). From this end point 82,
the call is routed via the switch 14 to the destination end
terminal 12. Triggers are available not only in the
originating network on messages from the source terminal but
also in the destination network on messages intended for the
10 destination terminal.

The above type of secure service can be made available
anywhere in the world provided subscribers are visiting areas
covered by roaming agreements with their home network
15 operator. These services can be run from any terminal because
the manner of operation means they are actually effected on
the network. All of the earlier mentioned advantages apply to
such roaming methods.

20 In order for originating and terminating end points to
decipher encrypted (or compressed) data, they must have access
to the relevant decryption (or de-compression) algorithms
and/or keys and be able to run them. In the cases of the
methods of Figures 2 and 3, the encryption end points 40,80
25 and 42,82 need to be provided with the relevant
encryption/decryption information. It is desired that only
those for whom the message is intended can access the
algorithms and/or keys which enable the message to be
deciphered. Moreover, these keys should not be distributed
30 over insecure networks. Where transmission of decryption
information is unavoidable, it should be distributed over
networks in a secure manner.

Two trusted network operators such as the operators of the
35 first and second networks (A) and (B) would normally have
access to corresponding encryption/decryption keys.
Nevertheless, the subscriber may still prefer to pay extra for
specific algorithm services which in effect function as an
additional layer of encryption or represent a specific tunnel
40 construction. In addition to the Internet 22, insecure
intermediate networks may include fixed and mobile networks

5 over which the network operator cannot offer the standard of encryption required. Where this situation occurs, security beyond the basic ciphering provided in for example GSM networks (and future UMTS networks) may be required by network users. When such additional protection is required, the
10 destination end point 42 and/or the destination end terminal 12 must have access to the necessary decryption information which is typically an algorithm or a key. The intelligent triggered method of Figure 4 works by querying a security server connected in an intelligent network as an intelligent
15 peripheral as described below.

Figure 4 schematically shows a preferred method for the distribution of encryption/decryption information. The illustrated network uses an algorithm/key distribution system
20 managed by intelligent network elements 30. The arrangement of Fig. 4 is similar to that of Fig. 2 and like reference numerals indicate like features. A first end terminal 10 wishes to communicate with a second end terminal 12 in a secure manner. The originating end terminal 10 is in a first
25 network (A) controlled by a first network operator and the second end terminal 12 is located in a second network (B) controlled by a second network operator. The networks (A) and (B) may be fixed or mobile networks operated by trusted network operators and are thus deemed relatively secure. In
30 order for the message content to traverse the Internet 22 in a secure manner it will need to be encrypted at or before the tunnel end point defined by encryption engine 40 and decrypted at or once it has passed end point 42. Thus it is possible for encryption/decryption to occur at nodes within either of
35 the networks (A) and (B) (e.g. encryption engine 40 or end point 42). Alternatively, it is possible for encryption/decryption to occur at the end terminals 10,12, respectively.

40 In operation, the end terminal 10 goes through the attach 50 and connection set up 52 procedures which inevitably depend on

5 the type of network. Service switching point 32 handles the
request for communication and, if present, a trigger causes
the service switching point 32 to refer to the service control
point 34. Examples of the various types of trigger set-up
10 and 3. The SCP 34 provides an intelligent function and can
refer to a subscriber profile in the service database 36. The
subscriber profile provides subscriber specific encryption
information and may also provide routing preferences. The
service control point 34 then communicates with the service
15 switching point 32 to route the transfer either through the
PSTN 16 or via the Internet 22. Where the subscriber profile
in service database 36 specifies encryption, the message is
routed to the encryption engine 40 and onwards to switch 18
via the Internet 22. There is a corresponding end point 42
20 where the message is decrypted within the secure network (B).
It would of course be possible for the relevant decryption to
be performed at the end terminal 12.

An intelligent network service management access point (SMAP)
25 100 allows the operator to alter records in the database 36
and, therefore, specify, load and change the algorithms or
keys to be stored and/or distributed. Accordingly, a given
subscriber can manage his own key hierarchy by instructing the
network operator to make, delete or alter relevant entries in
30 the database 36.

Note that the network (A) includes intelligent network
elements 30 and the service database 36 containing security
information managed by the operator of network (A). An
35 intelligent peripheral could also hold security information,
for example keys. The security information stored in service
database 36 might include encryption algorithms, compression
algorithms, keys 39, secure numbers or bitstrings etc. for use
in connection with electronic cash applications. As before,
40 where this security information is held within or is
associated with a given subscriber profile, it can be

5 proprietary to a specific subscriber. A selection of different
algorithms or keys may be held in association with a specific
group of subscribers. More than one algorithm/key may be
stored in the service database 36 with the various items being
held in a hierarchy along with specific instructions for use
10 thereof.

Preferred network arrangements can be set up to automatically
communicate the particulars of encryption or indeed whether or
not encryption is required at all. Preferred networks can be
15 set up to ensure decryption algorithm/keys are received by the
or each destination end terminal, either at the same time or
at a different time to the message itself. That is, any one
who was targeted as a recipient of a message can automatically
receive the relevant decryption information. As before, the
20 effect can be to create a virtual private network between
communicating end terminals.

Where a message is a broadcast message intended for a target
group consisting of a number of end terminals 12, a plurality
25 of keys 39 can be distributed simultaneously for the plurality
of target end terminals 12. Since the second network (B) is
deemed to be secure, it is not necessary for terminating end
terminals 10,12 to run decryption applications nor handle any
type of algorithm/keys at all. Encryption or decryption can be
30 performed at any secure points within, for example, networks
(A) and (B) under the control of the intelligent functions as
described with reference to Figures 2 and 3. Thus it is
possible for preferred embodiments to distribute security
information such as encryption/decryption information to a
35 node within a secure network, rather than the destination end
terminal for the communication in question (see also Figure 6
and 7). In such cases the receiving node in the secure
network acts on behalf of the destination end terminal to
proxy the relevant service, e.g. decryption.

40

However, in certain circumstances it may be that distribution

5 of decryption information, for example keys, to end terminals
is preferred and this is also possible provided the or each
end terminal in question is provided with the means necessary
to run the decryption application. The distribution of a key
10 need not be triggered specifically by a message content
associated with a call. The intelligent network may, for
example, periodically distribute keys or other security
numbers/information to selected nodes, end points or end
terminals or in response to external events. Thus with a
preferred network incorporating an intelligent network
15 function for the distribution of encryption information, keys
can be distributed for any party attached to any point in the
network and the distribution process can be network initiated.
That is network-initiated key up dates can be propagated to
secure end points 42 within the destination network or
20 directly to end terminals 12 of subscribers between sessions
or calls. The network-initiated periodic update may be to the
or each user selectively or it may be to one or more of the
operators and the distribution thereafter managed by the
operator. Similarly, any modifications or changes to
25 algorithms/keys or the key hierarchy can be specified and
transmitted to destination nodes with great efficiency.

The timings of network-initiated key distributions can be
selected to maximise security. For example, the keys may not
30 be distributed simultaneously with the messages they may be
distributed at different predetermined times which may be
regular or irregular times. All of the above services would
be available on a fixed network or on a mobile network and in
the latter case switching on or moving, for example, may be
35 used as triggers to push encryption information updates around
the various networks.

In mobile networks where the originating and/or terminating
end terminal is visiting another operator's network, the
40 service may be offered in accordance with roaming agreements.
Preferably, trusted communications between reputable network

5 operators will permit a virtual home environment (VHE) to be provided to visiting mobile terminals and, therefore, a subscriber could have access to the service anywhere in the world provided the local network is party to such an agreement. A virtual home environment is facilitated when
10 information concerning all aspects of the service possibly including encryption/decryption information, is shared between network operators in a secure manner.

Recipient end terminal users can specify that they wish to
15 answer calls only according to certain circumstances. For example, they may choose not to answer any calls which are not accompanied by keys or for which they do not have access to keys.

20 Public keys can be securely distributed to target subscribers over usually insecure intermediate networks for use with a private key service held at a secure location within one of networks (A) or (B). Alternatively, private keys may be distributed specifically to the service subscriber for him to
25 use exclusively in signing certificates or data. This service has obvious advantages over a system in which keys are distributed in a non-specific manner.

Signed certificate data can be verified by the public key
30 distributed to other parties needing authentication of the sender. Where public keys are made available by general broadcast or held at specific sites it is desirable for the validity of the key to be certified by some authority. Network operators may authenticate signed data/keys (i.e. act
35 as a certification authority) and, where appropriate, charge for the service.

In cases of secure symmetric encryption, a shared (secret) key can be distributed for secure sessions between two or more end
40 terminals 10,12 wishing to form secure connections across one or more usually insecure networks. Secure encryption

5 techniques are possible because the intelligent network elements 30 and particularly the tunnel entry 40 and tunnel exit 42 end points are located within networks owned by trusted network operators using network specific (e.g. GPRS or GSM) encryption.

10

The intelligent network function for the distribution of encryption information may be provided in originating network (A) or terminating network (B). In fact, one or more intelligent network elements may be provided in either or both ends of the communication chain. Figure 5 shows an arrangement in which intelligent network elements 60 are provided at the destination end of the communication chain. In order to communicate a message, the end terminal 10 would go through the usual access 50 and connection set up 52 procedures, regardless of whether the switch 14 in network (A) is in fact a telecommunication switch, an MSC or a type of intelligent network element. Assume also that switch 14 is operable to direct the transfer via the Internet 22 in an encrypted form. The message would thus be routed to a first tunnel end point, in this case defined by encryption engine 40. The exit to the tunnel 41 is defined by a second tunnel end point 42 from where the message is routed to intelligent network elements 60.

30 When the message reaches the group of intelligent network elements 60 it is received by service switching point 62. If a trigger has been set up and is identified, the service switching point 62 refers to the service control point 64. SCP 64 provides an intelligent function and accesses the service database 66 to get information on the algorithm or key relevant to the message in question. Information in the service database 66 can be associated with the message by any suitable means, e.g. by the ID of the originating subscriber or the destination number. In fact, the trigger may operate in response to any address message, ID, IP address, flow ID or payload information etc. The relevant encryption information,

40

5 in this case key 69, is transmitted back to the service control point 64 and then on to the service switching point 62 for transfer directly to the destination end terminal 12.

10 All advantages described in relation to the method of Figure 4 also apply here. For example, subscribers are able to control and manage their own key hierarchy in the same way as described with reference to Figure 4.

Clearly, the or each group of intelligent network elements 15 30,60 providing the triggering and distribution functions can be positioned at any convenient point in the communication chain, provided that the chosen location is one within the secure networks. Further, the elements of the or each group of elements 30,60 providing the trigger (recognition) and 20 distribution functions, namely the service switching points 32,62 and the service control points 34,64 need not be in the same part of the distribution chain. That is, a first group of intelligent network elements 30 in network (A) can instruct a second group of intelligent network elements 60 in network (B) 25 to distribute a key (or algorithm) to one or more destination end terminals 12.

Where added encryption is required on usually secure networks (e.g. PSTN 16), it is possible to provide an arrangement 30 wherein the necessary encryption/decryption means 40,42 are provided in the communication chain at either end of the PSTN 16 network or on the end terminals 10,12.

Short message services (SMS) could be used to deliver keys. 35 However, under short message service conditions nothing would be automatic, i.e. the key would not necessarily be received when the call is received in which case it would need to be requested subsequently. Short message service delivery may not always be possible if the receiving party is analogue mobile 40 or fixed telephone. Preferred embodiments are therefore most effective when used with fixed or mobile terminals whereas GSM

5 mobile has the additional option of SMS services.

Under certain circumstances, it may be preferable for the security information such as keys to be delivered on control channels rather than on user channels.

10

A further embodiment is described with reference to Figure 6. In order to proxy electronic-payment on behalf of an end-terminal 10, storage in a network element such as service data base 36 may be provided for electronic-cash bitstrings or in
15 a separate network element such as an intelligent peripheral 38. Electronic-cash held in the electronic-payment network element 36,38 could transfer electronic-cash as electronic-cash bitstrings over the networks 16,12 in a secure manner to receiving end terminal 12 where payment is required. In other
20 circumstances payment may be made to end terminal 13 within the same secure network in a similar manner. This electronic-payment service is available to those end-terminals that have subscribed to these services and are recognised by their subscriber identities known via the service switching point
25 32. The subscriber on whose behalf the payment was made may then be billed by conventional means if necessary, that is by the network operators billing centre.

With reference to Figure 7, a network element, such as an
30 Intelligent Peripheral 38, may be provided in the secure network (A) to sign messages or certificates originating from an end-terminal 10 in the secure network (A) and destined for other communicating parties which are either within the same secure network such as the end terminal 13, or more likely to
35 an end terminal 12 in an insecure network such as the PSTN 16 or Internet 22 connected to the secure network. The switch 18 is shown to illustrate that a receiving end-terminal 12 can be connected to the PSTN 16 or the Internet 22 or both. Switch 18 need not be shown if a direct connection is made to the
40 PSTN 16 or the Internet 22.

5 The operator of network (A) can distribute the security
information to many end-terminals 10,12,13 in a group
simultaneously as a multicast to the group or as multiple
separate point-to-point communications. Group lists are
maintained by the operator of network (A) in the service data
10 base 36 and subscribers can be added/removed from the lists.
This allows distribution to more than one end-terminal
simultaneously on the occurrence of a single event such as a
network trigger from a connection set up, a specific command
from an end-terminal or a network-initiated distribution from
15 a periodic trigger or external event, for instance in the
knowledge that the old security information has been
compromised. The network operator thus controls a secure
network with many authenticated subscribers at many end-
terminals. This permits the secure distribution of
20 new/updated security information to many subscribers at the
occurrence of a single network event.

It is also possible for preferred embodiments to distribute
security information to a node within one or more of the first
25 and second secure networks, rather than the destination end
terminal for the communication in question. The receiving
node in the secure network can act on behalf of the end
terminal to proxy such services as encryption/decryption,
electronic payment or signing messages/certificates.

30 The schematic illustrations of preferred embodiments are not
intended to limit the invention to one or more of the specific
arrangements disclosed herein. For example, the or each of
the network elements for performing the invention may be
provided in any suitable arrangement(s) and one or more is
35 likely be provided in different hierarchical layers of the
relevant telecommunication network.

CLAIMS:

- 5 1. A network arrangement for the distribution of security information between a first node in a first secure network and one or more nodes in a second secure network, said first and second networks being separated by a relatively insecure network, wherein communications from said first node to one or
10 more of said second nodes via said relatively insecure network are encrypted, the network arrangement comprising one or more network elements operable to store security information and triggerable to distribute said security information in a secure manner from said first node to one or more target nodes
15 in said second secure network.
2. A network arrangement according to claim 1, which is operable to distribute security information including one or more of encryption algorithms; decryption algorithms; security
20 keys; and electronic cash bit strings.
3. A network arrangement according to claim 1 or 2, wherein the one or more network elements comprise switch means provided with control means, and storage means for storing
25 said encryption/decryption information.
4. A network arrangement according to claim 1, wherein said switch means is operable to selectively distribute security information in response to a predetermined type of
30 communication.
5. A network arrangement according to claim 4, wherein said predetermined type of communication is identified by means of originating subscriber characteristics, destination
35 subscriber characteristics, payload characteristics or network service characteristics.
6. A network arrangement according to claim 1, 2 or 3, wherein said distribution is triggered according to a

5 predetermined schedule.

7. A network arrangement according to any preceding claim, comprising a service management access point.

10 8. A network arrangement according to any preceding claim, wherein the security information is distributed to a node within one or more of the first secure network and second secure network, rather than the destination end terminal for the communication in question.

15 .

9. A network arrangement according to any of claims 1-7, wherein the security information is distributed to the end terminal for the communication in question.

20 10. A network arrangement according to any preceding claim, wherein the one or more network elements distributes security information from a location substantially within the first secure network.

25 11. A network arrangement according to any preceding claim, wherein the one or more network elements distributes the security information from a location substantially within one of the first or second networks.

30 12. A network arrangement according to claim 11, wherein security information is transferred to the one or more network elements located in the second secure network by means of a secure communication route operated by trusted network operators.

35

13. A network arrangement according to claim 12, wherein security information is transferred to the one or more network elements located in the second secure network by means of a secure communication route over a relatively insecure
40 intermediate network.

5 14. A network arrangement for the distribution of security
information between a first node and one or more second nodes,
including one or more network elements operable to store
security information and triggerable to distribute the
security information from said first node to one or more of
10 said second nodes.

15 15. A network arrangement for the distribution of security
information between a node in a first secure network and one
or more nodes in a second secure network, said first and
15 second networks being separated by a relatively insecure
intermediate network, including:

in at least one of said first and second secure networks one
or more network elements operable to store security
information and triggerable to distribute security information
20 to one or more target nodes in said second secure network; and
an encryption engine for encrypting a communication before
it traverses said intermediate network.

25 16. A method for the distribution of security information
between a first node and one or more second nodes, including
the step of providing one or more network elements operable
to store security information and triggerable to distribute
the security information from said first node to one or more
target nodes.

30 17. A method for the distribution of security information
between a first node in a first secure network and one or more
nodes in a second secure network, said first and second
networks being separated by a relatively insecure network,
35 wherein communications from said first node to one or more of
said second nodes via said relatively insecure network are
encrypted, including the step of providing one or more network
elements operable to store security information and
triggerable to distribute security information in a secure
40 manner from said first node to one or more target nodes in
said second secure network.

- 5 18. A method according to claim 16 or 17, provided to a subscriber in a visited network by virtue of a roaming agreement between the operator of the visited network and the operator of the subscriber's home network.
